

Looser depression casts a wider genetic net

Genetic correlation with depression defined by clinical assessment and from health records

○ clinical assessment → health records (EHR) → difference $p < 0.05$ █ noise, 1.96 SE

READING THIS

EHR-defined depression correlates more strongly in 25 of 31; 6 reach $p < 0.05$, 0 survive Bonferroni. The two definitions correlate at 0.857 (SE 0.045), and clinical heritability is 0.114 against 0.057. The two GWAS share almost no people, so their noise does not cancel and single differences stay wide.
