

Shared cases, not sample size, decide how small a shift can be seen

Smallest difference in genetic correlation detectable 4 times in 5, by error correlation and SE

READING THIS

The same SE buys a shift of 0.20 with no shared cases, and 0.04 when the errors correlate 0.95. Sleep apnoea, adding primary care: SE 0.024, detects 0.015. EHR vs clinical: SE 0.039, detects 0.15. The map assumes equal SEs; 93% of comparisons sit in the band of their exact detectable shift.
